

Normalization exercises

Francesco Di Giacomo, Ahmad Omar

Note: For each of the following exercises complete the following tasks:

1. (Complete after lesson 1) Find what normal form each of the following tables satisfies. Motivate the answer according to the definition of normal forms seen in class.
2. (Complete after lesson 2) Apply the normalization algorithms seen in class to each table. Use intermediate refinements, i.e. if the table is in 1NF first normalize in 2NF and, if necessary, in BCNF.

Exercise 1 - Lockers The table is in no normal form, since it contains a multi-value attribute.

teacher		
<u>teacher_id</u>	name	surname

locker			
<u>id</u>	<u>teacher_id</u>	key_num	size

In **locker** the attribute **teacher_id** is a foreign key to **teacher**. The table is already in BCNF since all dependencies have the left argument which is a superkey.

Exercise 2 - Library The table is in no normal form since it contains a multi-value attribute.

1NF:

library		
<u>card_num</u>	name	surname

borrowed_books				
<u>author</u>	<u>car_num</u>	<u>title</u>	<u>date</u>	return_date

In **member** the attribute **card_num** is a foreign key to **library**.

2NF:

BCNF:

The tables created at the previous step are in 2NF because no functional dependencies exist. All the tables at this point are in BCNF because all the dependencies have a superkey as left argument.

Exercise 3 - Books 1NF:

The table is already in 1NF because all the attributes are atomic.

2NF:

Both dependencies have the left argument that is part of a key and the right argument that is a non-key attribute, thus they break 2NF

book	
<u>author</u>	<u>title</u>

book_author	
<u>author</u>	author_bdate

description			
<u>title</u>	genre	page	section

In the table **book** the attribute author is a foreign key to **book_author** and title is a foreign key to **description**.

BCNF:

All the tables are already in BCNF since the left argument of all the dependencies are superkeys.

Exercise 4 - Houses The table is in no normal form because it contains a multi-value attribute.

1NF:

houses				
<u>owner</u>	<u>postal_code</u>	price	size	account

owner_address				
<u>owner</u>	<u>postal_code</u>	<u>city</u>	<u>street</u>	<u>number</u>

In **owner_address** the attribute postal_code is a foreign key to **houses**

2NF:

Using the decomposition rule on $\text{postal_code} \rightarrow \text{price, size}$ we get the functional dependencies $\text{postal_code} \rightarrow \text{price}$ and $\text{postal_code} \rightarrow \text{size}$. Both break the 2NF because they are partially dependent on the primary key. Also the dependency $\text{owner} \rightarrow \text{account}$ breaks 2NF.

account	
<u>owner</u>	account

property		
<u>postal_code</u>	price	size

owner_address				
<u>owner</u>	<u>postal_code</u>	<u>city</u>	<u>street</u>	<u>number</u>

In **houses** the attribute **owner** is a foreign key to **account** and **postal_code** is a foreign key to **property**

BCNF:

All tables are already in BCNF because the left argument of all the dependencies is a superkey.

Exercise 5 - Port 1NF:

The table is already in 1NF because all attributes are atomic

2NF:

The dependencies **ship_name** \rightarrow **docked_at, country, weight, class** and **captain** \rightarrow **cpt_license** break the 2NF because the left argument is part of a key and the right argument is a non-key attribute (again use the decomposition rule). Note that the dependency **docked_at** \rightarrow **country** does not break 2NF because the left argument is not part of any key (the 2NF only considers dependencies where the left side is part of a key)

ship_captain	
<u>ship_name</u>	<u>captain</u>

ship				
<u>ship_name</u>	weight	class	docked_at	country

license	
<u>captain</u>	cpt_license

In **ship_captain** the attribute **ship_name** is foreign key to **ship** and **captain** is a foreign key to **license**.

BCNF:

The dependency **docked_at** \rightarrow **country** breaks BCNF because the left argument is not a superkey. The table **ship** must be decomposed in BCNF.

In the table **ship** the attribute **docked_at** is a foreign key to **docking**.

ship			
<u>ship_name</u>	weight	class	docked_at

docking	
<u>docked_at</u>	country

Exercise 6 - Cellar 1NF:

The table is in 1NF because it contains only atomic attributes

2NF:

The dependencies **producer** \rightarrow **country,location** and **wine** \rightarrow **bottling_date,price/l,grape-variety** break the 2NF since the left side is part of a key and the right side is a non-key attribute. The other dependencies do not break 2NF because they do not have a left argument that is part of a key

cellar	
<u>producer</u>	<u>wine</u>

producer		
<u>producer</u>	country	location

wine			
<u>wine</u>	bottling_date	price/l	grape_variety

In **cellar** the attribute **producer** is a foreign key to the table **producer** and the attribute **wine** is a foreign key to the table **wine**.

BCNF:

The dependencies **location** \rightarrow **country** **grape_variety** \rightarrow **price/l** break BCNF because their left argument is not a superkey. The tables **wine** and **producer** must be normalized in BCNF.

producer	
<u>producer</u>	location

location	
<u>location</u>	country

wine		
<u>wine</u>	bottling_date	grape_variety

grape	
<u>grape_variety</u>	price/l

In the table **wine** the attribute **grape_variety** is foreign key to **grape** and in the table **producer** the attribute **location** is foreign key to the table **location**.

Note: The following exercises are analogous to the previous exercises so only the final solution can be found

Exercise 7 - Courses In `teaching` the attribute `employee_code` is a foreign key to `employee` and the attribute `course_code` is a foreign key to `course`. In the table `course` the attribute `study_points` is a foreign key to `hours`.

teaching	
<u>employee_code</u>	<u>course_code</u>

employee		
<u>employee_code</u>	name	surname

course		
<u>course_code</u>	course_name	study_points

hours	
<u>study_points</u>	hours

Exercise 8 - Flights In the table `flying` the attribute `flight_code` is a foreign key to `flight`, and the attribute `captain_code` is a foreign key to `captain`. In the table `flight` the attributes { `departure`, `arrival` } are a foreign key to `duration`.

flying	
<u>flight_code</u>	<u>captain_code</u>

flight			
<u>flight_code</u>	plane_model	departure	arrival

captain	
<u>captain_code</u>	captain_name

duration		
<u>departure</u>	<u>arrival</u>	flight_time

Exercise 9 - Buildings In `materials` the attribute `building_type_code` is a foreign key to `building` and `material` is a foreign key to the table `material`. In the table `building` the attributes { `length,width,height` } are a foreign key to `taxes`.

building_materials		
<u>building_code</u>	<u>component_type</u>	<u>material</u>

material		
<u>material</u>	aximum_pressure	specific_weight

building			
<u>building_code</u>	building_length	building_width	building_height

taxes			
<u>building_length</u>	<u>building_width</u>	<u>building_height</u>	tax_rate
