Introduction

Indexing and Query optimization

Introduction

Query optimization

Problematic queries

WHERE

SORTING

JOIN

Lecture topics

- Query optimization.
- Examples of slow query operations.
- Hashing.
- Trees.

Indexing and Query optimization

Introduction

Query optimization

Problematic queries

WHERE

SORTING

JOIN

Reasons

- Query needs to be fast.
- Sometimes they are not.
- You do not want to see your nephew born before retrieving the book you are looking for from Amazon.

Indexing and Query optimization

Introduction

Query optimization

Problematic queries

WHERE

SORTING

JOIN

Causes

- Too much data (Big data analysis).
 - Data clustering.
 - Better hardware. (arrays of disks, caching, ...)
- Too complex queries (DBMS optimization)
 - Refactor query. (Access planner)
 - Refactor data. (Indexing)

Indexing and Query optimization

Introduction

Query optimization

Problematic queries

WHERE

SORTING

JOIN

- Query refactoring not always possible.
- Build additional data to speed up the data retrieval.

Indexing and Query optimization

Introduction

Query optimization

Problematic queries

Problematic queries

WHERE

SORTING

JOIN

- How many comparisons we do at most in a table with R records?
- R comparisons
- How many comparisons we do at least in a table with R records?
- R comparisons
- Selection always requires to scan the entire table.

SORTING

Indexing and Query optimization

Introduction

Query optimization

Problematic queries

WHERE

SORTING

JOIN

Sorting and grouping requires to sort the column values.

- The best sorting algorithm requires about $R \log R$ operations, where R is the number of records.
- Running the query below requires about $10*\log 10 \simeq 23$ operations.

SELECT type FROM ships WHERE firepower = 500 ORDER BY name DESC

Indexing and Query optimization

Introduction

Query optimization

Problematic gueries

WHERE

SORTING

JOIN

 Generate pairs with one element from the first table and the second from the other followed by a selection.

- Same problem of the selection.
- Consider the following query applied to ship and the table below.

```
SELECT s.name,p.damage
FROM ships s,projectiles p
WHERE s.position = p.position AND
s.name = p.target
```

Projectiles					
target	position	damage			
Red 3	(0,1,0)	30			
Red 3	(3,1,-2)	50			
Red 3	(0,2.5,1)	100

Dictionaries and Indices

- A Dictionary is a collection of entries.
- An entry is a pair $\langle key, value \rangle$.
- An index can be thought as a dictionary. The key is the search parameter in the index.

Indexing and Query optimization

Introduction

Query optimization

Problematic gueries

WHERE

SORTING

JOIN

Hash table

- It is an array of buckets. Each element of the array is a pointer to a specific bucket.
- A bucket is an array used to contain data.
- Insertion uses a *hash function* to map a key to a position in the array.
- The hash function always returns a value between 0 and array.length - 1.
- Use the hash function to search for a key and go to the corresponding bucket.

 What is the cost of the join with a hash index on name^a?

Indexing and Query optimization

Introduction

Query optimization

Problematic queries

WHERE

SORTING

JOIN

Performance (WHERE)

- What is the cost of the join with a hash index on name^a?
- For each record in projectile we need to access the bucket in the other table
- The only record which matches in ship is 'Red 3'.
- We apply the hash function and read the entry in the hash table for 'Red 3'. This means $3 \cdot 2 = 6$ operations to select the ships in both table with the same name.
- In total we have 6 + 30 operations = 36 operations (30 for the non-indexed attribute in the condition).

^aAssume that the index maps the starting letter of its position in the alphabet order and no collisions

Indexing and Query optimization

Performance (WHERE)

• What if we also have an index on position?

Indexing and Query optimization

Introduction

Query optimization

Problematic queries

WHERE

SORTING

JOIN

Performance (WHERE)

- What if we also have an index on position?
- There is one entity in the ships table which matches the condition.
- For each record in projectiles we look for a record in ships with the same position.
- 2 records mismatch the position and one matches.
- Accessing the mismatching records requires 2 operations (we only need to hash the search key to find it is not in the buckets). Accessing the matching record requires 2 operations. In total 4 operations.
- With two indices we require only 6 + 4 = 10 operations.

Indexing and Query optimization

Introduction

Query optimization

Problematic queries

WHERE

SORTING

JOIN

Drawbacks of hash tables

- Useless if the condition is not an equality but an inequality (conditions on intervals).
- Useless with ordering/grouping commands.
- A lot of collisions require to extend the buckets/slow down the search if overflow buckets are used.

Indexing and Query optimization

Introduction

Query optimization

Problematic queries

. WHERE

SORTING

JOIN

Balanced trees

- A graph is a set of vertices connected by edges.
- A tree is a graph without cycles and connected (all nodes can be reached following connections from a starting node).
- The top node is called root.
- The nodes that are directly connected to a node and at a deeper level are called children. The children shares the same parent.
- A node which does not have children is called *leaf*.
- A balanced tree is a tree where the leaves are all at the same level.

Indexing and Query optimization

Introduction

Query optimization

Problematic queries

WHERE

SORTING

JOIN

2-3 Trees

- Balanced tree.
- Every node contains at most 2 entries
- Every node has 2 or 3 children.
- The keys in the left child are less than or equal to the keys in the parent.
- The keys in the middle child are between the min and the max keys stored in the parent.
- The keys in the right child are greater than or equal to the keys in the parent.

Introduction

Query optimization

Problematic queries

WHERE

SORTING

JOIN

Performance (JOIN)

- What is the cost of the join with a 2-3 tree index on name in table ships (see the next slide for the index) a?
- This time the inner table in the for-loop is ships.
- We need to find 'Red 3' three times in the index. This requires to traverse the whole three 3 times and each time we access the record, for a total of 12 operations.
- We have 12 operations vs the required 30 without indexing.
- In total we have 42 operations vs 60 (position is not indexed).
- This is a very unlucky case, since the entry is stored in a leaf. Imagine we were looking for "Red 4", we would need just 1 operation to get to the correct node.

Anguage that the index many the starting letter of its position in the

Ordering/grouping with trees

- A clustered index is an index where the record order in a file is the same in the index.
- If the tree index is clustered we can use the tree for ordering/grouping.
- Just traverse the tree. If the ordering is ascending then visit all the nodes starting from the leftmost and then moving to the rightmost.
- This requires N steps where N is the number of entries in the index (vs $N \log N$ of a traditional ordering algorithm).

Overall evaluation of trees

- Fast with conditions on intervals.
- Fast with ordering/group by.
- The worst case requires to scan $\log N$ entries before finding our entries (with Hash tables it is at most the size of the largest bucket).

Indexing and Query optimization

Introduction

Query optimization

Problematic queries

WHERE

JOIN

Golden rules of indexing

- If most of the queries have selections/joins with equalities choose hash tables.
- If most of the queries have selections/joins with inequalities choose trees.
- If you can anticipate there will be a lot of mismatches in the comparisons choose hash tables.
- If you anticipate there will be a lot of collisions (a lot of duplicate values) choose trees.
- If you have a lot of queries with ordering/group by use clustered trees (otherwise do not use clustering).
